

DSO 545: Statistical Computing and Data Visualization

Abbass Al Sharif

Fall 2019

Lab 1: Python Variables and Lists

Contents

- Python for Computations
 - Variables in Python
 - Types of Variables
 - Python Lists Data Structure
 - Accessing Elements of Lists in Python
 - Selected Methods for Python Lists
 - Python Dictionaries Data Structure
-

1. Python for Computations

1. Perform the some computations in Python using the arithmetic signs $+$, $-$, $/$, $*$, $**$,

2. Variables in Python

2. Create three variables: one to store your height in meters (height), weight in kilograms (weight), and body mass index (bmi).
3. Using the code you created in the previous question, calculate the bmi for a person whose weight is 71Kg and height is 2m.
4. Create a variable called x, and store a value of 5 in it.
5. Update the stored value of the x variable that was defined in the previous question by incrementing it by 1.
6. Define three variables x, y, and z, and assign the values of 45, “Marshall”, and “DSO 545” to each.

3. Types of Data or Variables

7. What type of data structures do the x and bmi variables have? What about the type of the constant “DSO 545”?
8. Define a variable x with value of 2.5. Try to convert the data type of x to integer. Try to convert/cast it to a string.

4. Python “List” Data Structure

9. Create a list of the following numbers: 1, 4, 9, 25, 36, 49, 64. Name this list `squares`.
10. The previous list was homogenous, i.e. all elements were of the same type. Create a mixed list of numbers and strings for the following: “one”, 1, “four”, 4, “nine”, 9, “twenty five”, 25. Name this list `mixed_list`.
11. Given that lists allow store to have any data type/structure, list’s try to create a list of lists! Assign each string and numeric value in the previous question to a list, i.e. [‘one’, 1] etc. Store all of the sublists in one list and name it `list_of_lists`.

5. Accessing Elements of Lists in Python

12. Access and print the first element of the `squares` list defined earlier.
13. Access and print the third and sixth element in the `squares` list.
14. Access and print the last element in the list `squares`.

List Slicing: We can access a range of items in a list by using the “colon” slicing operator (:). The following rules apply to slicing (<https://www.geeksforgeeks.org/python-list/>):

List Slicing	Code
To print elements from beginning to a range	<code>[:Index]</code>
To print elements from specific <code>Index</code> till the end	<code>[Index:]</code>
To print elements within a range	<code>[Start Index:End Index]</code>
To print every other nth element in the list	<code>[::n]</code>
To print whole List in reverse order	<code>[::-1]</code>

15. Access and print the first 3 elements in the `squares` list.
16. Access and print the all elements in the `squares` list starting at 5th element.
17. Access and print the all elements in the `squares` list starting at 3rd element, and ending at the 5th element.
18. Access and print every other 3rd element in the list.
19. Access and print all elements of the list in reverse order.
20. Access and print every other (second) element of the list in reverse order:
21. Define a list that contains the elements: 30, 60, 70, 100, 120. Update the third element to be 95.
22. Update the 2nd, 3rd, and 4th elements in x to 55, 65, and 95.

6. Iterating over a Python List

Method 1: Using a For loop

23. Use a for loop to print all the elements in `list = [1, 3, 5, 7, 9]`.
24. Create a list (`degrees = [0, 10, 20, 40, 100]`). Print the following output:

```
## list element: 0
## list element: 10
```

```
## list element: 20
## list element: 40
## list element: 100

## The degrees list has 5 elements
```

Method #2: For loop and range()

25. Use the `range()` function in a for loop to print numbers from 0 to 5.
26. Use the `range()` function to print all the elements in (`list = [1, 3, 5, 7, 9]`).

Method #3: Using list comprehension

27. Use a list comprehension to print all the elements of (`list = [1, 2, 3, 4, 5, 6, 7, 8, 9]`).
28. Use a list comprehension to create a list of all the squared values of the list (`list = [1, 2, 3, 4, 5, 6, 7, 8, 9]`).
29. Use a list comprehension to print all the even numbers in the list (`list = [1, 2, 3, 4, 5, 6, 7, 8, 9]`).

7. Selected Methods for Python Lists

Methods that are available with list object in Python programming are tabulated below (<https://www.programiz.com/python-programming/list>):

Method	Description
<code>append()</code>	Add an element to the end of the list
<code>extend()</code>	Add all elements of a list to the another list
<code>insert()</code>	Insert an item at the defined index
<code>remove()</code>	Removes an item from the list
<code>clear()</code>	Removes all items from the list
<code>index()</code>	Returns the index of the first matched item
<code>count()</code>	Returns the count of number of items passed as an argument
<code>sort()</code>	Sort items in a list in ascending order
<code>reverse()</code>	Reverse the order of items in the list

30. Add the element 150 to the end of list (`x = [30, 60, 70, 100, 120]`).
31. Add the list `[170, 180, 190]` to the end of the list (`x = [30, 60, 70, 100, 120]`).
32. Insert the element 50 to the list (`x = [30, 60, 70, 100, 120]`). Insert this element directly after 30.
33. Delete the element 50 from the list defined in the previous question.
34. What is the index position of the element 70 in the list (`x = [30, 50, 60, 70, 100, 120]`).
35. How many times does the element 50 appear in the list (`x = [30, 50, 50, 50, 50, 60, 70, 100, 120]`).
36. Sort the elements of the list (`x = [60, 20, 90, 35, 15]`).
37. Sort the elements of the list (`x = [60, 20, 90, 35, 15]`) in reverse order.
38. Print the elements of the list (`x = [60, 20, 90, 35, 15]`) in reverse order.

8. Python “Dictionaries” Data Structure

39. Define a dictionary data structure as follows: the keys for the dictionary represents countries (Peru, Armenia, Jordan, and Norway), and the values represent their capitals (Lima, Yerevan, Amman, Oslo).

40. Access and print the capitals of Peru and Jordan.

Note that, you can also build the dictionary incrementally as follows:

```
person = {} #initialize the dictionary
type(person)
```

```
## <class 'dict'>
```

```
person['fname'] = 'Joe'
person['lname'] = 'Fonebone'
person['age'] = 51
person['spouse'] = 'Edna'
person['children'] = ['Ralph', 'Betty', 'Joey']
person['pets'] = {'dog': 'Fido', 'cat': 'Sox'}
```

```
print(person)
```

```
## {'fname': 'Joe', 'lname': 'Fonebone', 'age': 51, 'spouse': 'Edna', 'children': ['Ralph', 'Betty', 'Joey'], 'pets': {'dog': 'Fido', 'cat': 'Sox'}}
```

We can access elements as follows:

```
person['fname']
```

```
## 'Joe'
```

```
person['children']
```

```
## ['Ralph', 'Betty', 'Joey']
```

What if we want to access the third child in the list of children?

```
kids = person['children']
kids[2]
```

```
## OR
```

```
## 'Joey'
```

```
person['children'][2]
```

```
## 'Joey'
```

41. Create two lists separately, one for the countries ('Peru', 'Armenia', 'Jordan', 'Norway'), and the other for the cities (Lima, 'Yerevan', 'Amman', 'Oslo'). Create a dictionary called **capitals** where the countries are the keys and cities are the values of the dictionary.
